9 Wrap up	153

1 Preliminaries

This R Markdown document was created in RStudio using the Knit Directory = *Document Directory* setting. The code assumes it will execute in the document directory, and depending on how you run this, you may have to set that manually, just above.

This R Markdown document was prepared using

R version:

```
R.Version()$version.string
```

```
## [1] "R version 4.0.3 (2020-10-10)"  
• RStudio version 1.2.1335  
• Additional R packages from CRAN  
– knitr
```

- bookdown
- formatR
- devtools
- reshape2
- ggplot2
- plyr
- stargazer
- xtable
- readr
- stringr
- httr

This document is distributed in R Markdown .Rmd and PDF .pdf documents. First load the necessary packages.

2 HMD Data

2.1 Download and parse HMD

First clear everything out, including directories where results will be stored.

```
rm(list = ls()) # clear R environment
system("rm -r ../data/HMD/*") # remove contents of HMD data directory
system("rm -r ../RData/*") # remove contents of Rdata directory
system("rm -r ../figures/*") # remove contents of figures directory
system("rm -r ../tables/*") # remove contents of tables directory
```

The data come from the Human Mortality Database (HMD) and are available online at www.mortality.org – [click here](#). The file *getHMD.R* contains a set of functions that automate downloading and parsing all of the HMD life tables. This code is not commented, but you can get the general gist of what's going on by reading it. In a nutshell, the HMD .zip file is downloaded and unzipped (if the HMD web site isn't working, a pre-downloaded version of the file from 2018-11-02 is used), and then all life tables of a specified type are read into a big R list that is very fast and flexible. Functions are provided for extracting a specified column from all life tables in such a list and outputting the result as a matrix. The following chunk sources the functions for automating downloading and processing of the HMD life tables.

```
# source('../R/getHMD.R') # load the 'read HMD'
# functions

# uncommented code to download the HMD Statistics file
# and organize the life tables into an
# easy-to-manipulate list
list.raw.lts <- function(hmd.dir, age, period) {

  lts <- list(female = read.raw.lt(hmd.dir, "female",
    age, period), male = read.raw.lt(hmd.dir, "male",
    age, period), both = read.raw.lt(hmd.dir, "both",
    age, period))

  return(lts)
}

read.raw.lt <- function(hmd.dir, sex, age, period) {
```

```

# <hmd.dir> must contain a string that specifies the
# location of the 'hmd_statistics' directory created
# when the HMD .zip file is unzipped.

```

The following chunk uses the download.hmd() function to download the HMD life tables. To run you need to insert your own HMD user name and password. The data are unzipped into the *data/HMD/hmd_statistics* directory that needs to exist before downloading.

```
# try the download
download.result <- download.hmd(
  output.file = "../data/HMD/hmd_statistics.zip",
  unzip.dir = "../data/HMD/hmd_statistics",
#####
##### IMPORTANT #####
#####
```

```

#   with following two lines commented, this script will use      #
#   archived HMD and replicate the article                      #
#   uncomment following two lines to download and analyse       #
#   current HMD                                              #
#####
hmd.user="sam@samclark.net",
hmd.pass="1241662754"
)
# if download.hmd() returns an error, then use the local cached copy of the HMD
if (class(download.result)=="try-error") {
  print(paste("Something went wrong -- usually this means the HMD site is not available.",
             " Using local cached version of HMD instead of a live download.",sep=""))
  unzip(zipfile="../data/HMD Archive/hmd_statistics.zip",exdir="../data/HMD/hmd_statistics")
}

```

The `download.result` object contains a description of what happened when the download was requested. You can have a look with this code.

```

if (class(download.result) != "try-error") {
  names(download.result)
  download.result
  download.result$date
  download.result$times
  download.result$headers
} else {
  print("Download did not happen, using local cached version of HMD.")
}

```

HMD nomenclature describes $age \times period$ life tables. For example 1×1 are single calendar year by single year of age, and 5×5 are five-year age groups by five-year periods, with the first age group broken into 0 and 1–4 years. The following code creates an R list for each of various commonly used life tables. The resulting lists are saved in the `RData` directory in compressed form. Unless it has been fixed between when I write this and when you execute it, the following code will produce errors for some of the Belarus files – those files do not contain data. Finally, if you use the HMD download functions on their own, make sure not to prepend ‘/’ or ‘./’ to the path for the `hmd_statistics` directory. Several errors will appear; these are due to several HMD life tables not having any values, at this time all from Belarus.

```

# set the download date if the download was successful
if (class(download.result) != "try-error") {
  download.date <- download.result$headers$date
} else {
  download.date <- "Local cached HMD"
}

# 1-year age x 1-year period life tables
hmd.1x1.list <- list.lts("../data/HMD/hmd_statistics", 1,
  1, download.date)
# arguments are path to 'hmd_statistics' directory age
# designator: either 1 or 5 year age groups period
# designator: either 1, 5, or 10 year age groups
save(file = "../RData/hmd-1x1.RData", compress = TRUE, list = c("hmd.1x1.list"))
# hmd.1x5.list <-
# list.lts('data/HMD/hmd_statistics', 1, 5, download.result$headers$date)
# save(file='../RData/hmd-1x5.RData',compress=TRUE,list=c('hmd.1x5.list'))
# hmd.1x10.list <

```

```

# list.lts('data/HMD/hmd_statistics',1,10,download.result$headers$date)
# save(file='../RData/hmd-1x10.RData',compress=TRUE,list=c('hmd.1x10.list'))

2.2 Clean HMD

There are two persistent problems with the HMD 1×1 life tables: 1. as mentioned just above, some of the Belarus life tables are empty, and 2. the $1q_x$ values for some life tables are ‘flat’ at older ages, i.e. are constant.

In both cases, these life tables need to be removed. We’ll get rid of the Belarus tables first. The strategy is general: identify life tables with ‘NA’ values and remove those. They turn out to be Belarus 1914–1918.

```

2.3 Additional Indicator Calculation

We need child, ${}_5q_0$, and adult, ${}_{45}q_{15}$, mortality values for females and males. Calculate these from the 1×1 nqx values and store in separate matrices, including the log and logit transformed values.

```

# function to generate 5q0 from a matrix of 1qx
convert1qxTo5q0 <- function(q1) {

  # q1 is an age by life table matrix of 1qx q5 is 1 by

```

```

# life table matrix/vector of 5q0

tmp.q <- rep(1, ncol(q1))
for (i in 1:5) {
  tmp.q <- tmp.q * (1 - q1[i, ])
}
q5 <- as.matrix(1 - tmp.q)
return(q5)
}

# function to generate 45q15 from a matrix of 1qx
convert1qxTo45q15 <- function(q1) {

  # q1 is an age by life table matrix of 1qx q5 is 1 by
  # life table matrix/vector of 45q15

  tmp.q <- rep(1, ncol(q1))
  for (i in 16:60) {
    tmp.q <- tmp.q * (1 - q1[i, ])
  }
  q5 <- as.matrix(1 - tmp.q)
  return(q5)
}

# now actually create the child and adult mortality
# indicators

# female

# make matrix with 5q0 in row 1 and 45q15 in row 2
Q.f <- rbind(t(convert1qxTo5q0(q1.f)), t(convert1qxTo45q15(q1.f)))
# check for zeroes
Q.f[Q.f == 0]

```

3 SVD Component Model of Mortality

3.1 *svdMod()* function

svdMod() is a function that wraps up most of the operations needed to calculate and validate SVD-Comp models. This function does a lot and can be used in a variety of ways:

- Calculate/estimate an SVD-component mortality model using a set of age-specific nq_x as inputs
- Calculate/estimate a smoothed SVD-component mortality model using a set of age-specific nq_x as inputs
- Randomly sample a set of age-specific nq_x , calculate an SVD-component model of mortality (smoothed or not), predict nq_x for the not-sampled age-specific nq_x , and summarize the prediction errors
- All of this can be repeated a specified number of times
- The return object contains very detailed results for everything that was requested

Inputs to the function:

- ‘ql’ are the logit-transformed input age-specific nq_x (life tables) arranged as age×lifetable
- ‘Ql’ are the logit-transformed summary mortality indicators: child mortality, ${}_5q_0$, and adult mortality, ${}_{45}q_{15}$, arranged in $2 \times n$ form where the first row is child mortality, the second adult mortality, and the columns correspond to life tables
- ‘N’ is the number of times to repeat sampling/validation
- ‘S’ is the fraction of life tables to include in the sample
- ‘offset’ is a number used to offset the the age-specific mortality rates from the origin before calculating the SVD; this is an easy way to give each age group approximately the same weight in the SVD calculation; it is added back when predictions are made
- ‘retAll’ is a switch indicating if all results should be returned or just summaries
- ‘adult’ is a switch indicating if adult mortality, ${}_{45}q_{15}$, is supplied and should be used directly as an input to the model when predictions are made; if not, then child mortality, ${}_5q_0$, is the only direct input, and adult mortality is used *indirectly* by predicting it from child mortality and then using it together with child mortality for the predictions for other ages
- ‘q0Fix’ is a switch indicating if the $q0$ fix should be executed during predition
- ‘smooth’ is a switch indicating if the SVD-comp model should be smoothed
- ‘C’ specifies the number of components to include in the SVD-component model

The return object is a large list that contains:

- ‘ql.samp’ - a list of the sampled age-specific nq_x , i.e. life tables, (one for each sample)
- ‘ql.nsamp’ - a list of the not sampled age-specific nq_x (one for each sample)
- ‘names’ - the names of the sampled life tables
- ‘svd’ - a list of the SVD decompositions (one for each sample) of the sampled life tables
- ‘svd.sm’ - a list of the smoothed SVD decompositions (one for each sample) of the sampled life tables
- ‘mods’ - a list of the the regression return objects (one for each sample) from the regression models for each SVD component weight in the model, the model for adult mortality, and the model for the q0 fix
- ‘recon.samp’ - a list of the predicted life tables (one for each sample) for life tables in the sample
- ‘error.samp’ - a list of the prediction errors (one for each sample) for the sampled life tables
- ‘recon.nsamp’ - a list of the predicted life tables (one for each sample) for life tables not in the sample
- ‘error.nsamp’ - a list of the prediction errors (one for each sample) for the not sampled life tables
- ‘errsum.samp’ - a list of summaries (one for each sample) of in-sample errors, uses R’s *summary()* function
- ‘errsum.nsamp’ - a list of summaries (one for each sample) of out-of-sample errors, uses R’s *summary()* function
- ‘offset’ - the *offset* value used when the function was called
- ‘retAll’ - the *retAll* value used when the function was called
- ‘adult’ - the *adult* value used when the function was called
- ‘q0fix’ - the *q0fix* value used when the function was called
- ‘smooth’ - the *smooth* value used when the function was called
- ‘C’ - the *C* value used when the function was called

A couple notes:

- The input age-specific nq_x must all be logit-transformed, the function assumes this and uses an *expit* transformation to do predictions on the natural scale
- The ‘mods’ return object is very useful for doing predictions and building additional modeling features using the return object of this function
- the ‘retAll’ option is included because full results can be *very* large, and returning the summaries is a much more compact way to do things if you need to run many times and don’t need the detailed results each time

3.2 *ltPredict()* function

ltPredict() is a function that uses a return object from *svdMod()* to predict new life tables.

Inputs to the function:

- ‘mods’ is an output object from *svdMod()*
- ‘smooth’ is a switch indicating if the smoothed left singular vectors should be used for the prediction
- ‘cml’ is a value/vector for the input level(s) of logit-scale child mortality, ${}_5q_0$
- ‘aml’ is a value/vector for the input level(s) of logit-scale adult mortality, ${}_45q_{15}$

The return object is:

- ‘r.p’ – a dataframe containing the predicted life table(s)

```

ltPredict <- function(mods, smooth, cml, aml) {

  # mods is an output object from svdMod() cml is a vector
  # of logit child mortality rates aml is a vector of
  # logit adult mortality rates if aml not supplied, then
  # aml predicted from cml smooth is a switch to use
  # smoothed SVD if it's available

  cm <- expit(cml)
  cmls <- cml^2
  cmhc <- cml^3
  preds.aml <- data.frame(cm = as.numeric(cm), cml = as.numeric(cml),
                           cmls = as.numeric(cmls), cmhc = as.numeric(cmhc))
  if (missing(aml)) {
    # predict adult mortality

```

4 Validation

First, run the *svdComp()* function with one iteration and a 100% sample in both ‘base’ and ‘smoothed’ form using only child mortality as a direct input, i.e. ‘adult’ is set to FALSE, and specifying two components. This will yield SVD-Comp models calibrated on the entire HMD data set. The *svdComp()* function provides a little feedback, here indicating that two-component models were run on one sample of 100% with the child mortality-only model, either base or smoothed.

```

# specify some key parameters, just to be a bit more
# readable!
adult <- FALSE
smooth <- FALSE
N <- 1
S <- 1
C <- 4
offset <- 10
# base model
mod.1_0.m <- svdMod(q1logit.m, Qlogit.m, N, S, offset, TRUE,

```

To compare the predicted results from the SVD-comp model calibrated with the entire HMD to results produced by Wilmoth et al.'s Log Quad model, we must calculate five-year age group probabilities of dying, tq_x , because Log Quad operates only with five-year age groups. The following code uses the single-year age group predictions from SVD-comp to calculate five-year age group probabilities of dying.

```

# fast functions to calculate a vector of 5qx for any
# five-year age group indexed from 0 by 1

# ages 1-4
oneToFourYear <- function(oneYear) {
  return(1 - prod(sapply(2:5, function(x, y) (1 - y[x]),
                        y = oneYear)))
}

# five-year age groups
fiveYear <- function(start, oneYear) {
  return(1 - prod(sapply((start * 5 + 1):(start * 5 +
                                         5), function(x, y) (1 - y[x]), y = oneYear)))
}

# fast function to convert full schedule of 1qx into
# full schedule of 5qx

```

```

fiveYearQ <- function(oneYear) {
  sapply(0:(trunc(length(oneYear)/5 - 1)), function(x,
    y) fiveYear(x, y), y = oneYear)
}

# fast function to calculate 45q15 from 1qx
adultQ <- function(oneYear) {
  return(1 - prod(sapply(16:60, function(x, y) (1 - y[x]),
    y = oneYear)))
}

# fast function to calculate 5q0 from standard 5qx
childQ5 <- function(fiveYear) {
  return(1 - prod(sapply(1:2, function(x, y) (1 - y[x]),
    y = fiveYear)))
}

# fast function to calculate 45q15 from 5qx
adultQ5 <- function(fiveYear) {
  return(1 - prod(sapply(5:13, function(x, y) (1 - y[x]),
    y = fiveYear)))
}

# fast function to calculate a full standard 5-year age
# schedule
standardFiveYear <- function(oneYear) {
  l <- trunc(length(oneYear)/5)
  c(oneYear[1], oneToFourYear(oneYear), fiveYearQ(oneYear)[2:l])
}

# examples using single age schedule of 1qx
# adultQ(<data>) fiveYearQ(<data>)
# standardFiveYear(<data>) using a matrix of age
# schedules of 1qx apply(data,2,<function:adultQ or
# fiveYearQ or standardFiveYear>)

# function to calculate a matrix of 5qx from a matrix of
# 1qx
convert1qxTo5qxApply <- function(q1) {

```

R code supplied by Wilmoth et al. is used to calculate the predicted five-year age group probabilities of dying using the Log Quad model using the same inputs as those used by SVD-Comp: the ${}_5q_0$ and ${}_5q_{15}$ values stored in the ‘Q.f’ and ‘Q.m’ matrices – logit-transformed (‘Qlogit.f’ and ‘Qlogit.m’) for SVD-Comp. For more information on the Log Quad model code download here (www.demog.berkeley.edu/~jrw/LogQuad). First create a function to do the comparisons.

```

# function to conduct comparison of predicted 5qx from SVD-Comp
# and Log-Quad
doComparison <- function(q1logit.f,Qlogit.f,q1logit.m,Qlogit.m
                          ,q5.f,q5.m,N,S,offset,adult,smooth,C) {

5 Plotting

Most plotting is done using *ggplot*. First load the necessary packages. The plots are not generated in the same order of appearance as the paper.

Plot the basic age \times age relationships among $5q_x$ for all ages and both sexes and save as (very large) PDF files.

```

# age relationships

# female
pdf(file = "../figures/femaleLogit(q)AgeScatterplots.pdf")

6 Make Tables

Load the Stargazer and xtable packages for making nice LaTeX tables from regression output. The code uses `capture.output()` to redirect output to text files where either complete LaTeX tables are stored, or the rows of LaTeX tables are stored. The rows-only tables slot nicely into headers and footers that are nicely formatted in the manuscript, and the whole tables (Stargazer output) are completely ready to go and slot straight into the LaTeX.

Create table describing which HMD life tables are included in the analysis.

```
# recall that the same life tables are used for females
# and males
all.equal(colnames(q1.f), paste("fe", colnames(q1.m), sep = ""))
## [1] TRUE
```

```

# data frame with the life table names with years
allLifetables <- read.table(text = colnames(q1.f), sep = ".",
  colClasses = "character")
colnames(allLifetables) <- c("sex", "country", "year")
allLifetables$year <- as.numeric(allLifetables$year)

# summarize life tables
country <- allLifetables[1, 2]
year <- allLifetables[1, 3]
ltList <- list()
ltList[[1]] <- c(country, year, "")
index <- 1
for (i in 2:nrow(allLifetables)) {

```

Create lines for age-specific error tables. These compare the l_x -weighted age-specific total absolute error (tae) in prediction between SVD-Comp and Log Quad. The coding strategy is to write a couple functions to automate this set of calculations so that it can be repeated several times later using different numbers of components in the SVD-Comp predictions. The first function *lthat()* creates full life tables from the SVD-Comp predictions – so that we can get age-specific expectations of life, e_x . The second function *ageSpecificErrorComparisons()* used the first and actually calculates the age-weighted prediction errors and their differences and organizes them into a nice return object.

```

# function to calculate life table from matrix of 1qx
lthat <- function(q, sex, a1.f, a1.m) {
  # calculate lx
  zeroes <- matrix(0, nrow = (nrow(q) + 1), ncol = ncol(q))
  l <- zeroes
  l[1, ] <- 1e+05 # l0 = 100000
  # loop through ages and calculate lx

```

```

for (i in 2:nrow(l)) {
  l[i, ] <- l[(i - 1), ] * (1 - q[(i - 1), ])
}
# calculate Lx
L <- zeroes
# loop through ages and calculate Lx
for (i in 1:(nrow(l) - 1)) {
  L[i, ] <- l[(i + 1), ] + ifelse(str_to_lower(sex) ==
    "female", a1.f[i, ], a1.m[i, ]) * (l[i, ] -
    l[(i + 1), ])
}

```

7 Test on Other Countries

SVD-Comp is tested on two different countries that are not part of the HMD and are not developed countries but for which reasonable data exist: Mexico and South Africa. Example life tables for Mexico (1983–1985) from the Human Life Table Database (www.lifetable.de) [<https://www.lifetable.de/data/hld.zip>] and South Africa (2005) come from the WHO's Global Health Observatory [<http://apps.who.int/gho/data/?theme=mai&nvid=61540>]. The life tables are converted to standard five-year age groups ending at ages 80-84, the oldest second-to-last age group that is common across both examples. Predictions are made with both SVD-Comp and Log Quad using both child and adult mortality as predictors, and both the data and those predictions are plotted.

```

# Mexico read 1983–1985 Mexican life tables from Human
# Life Table Database
mex <- read.csv("../data/non-HMD life tables/Mexico1983-1985.csv",

8 Make Compressed Models Object for Package

The SVD-Comp package predicts life tables using child or (child,adult) mortality as inputs. To do this calibrated by HMD, it needs all the component values and models calculated above. This piece of code wraps all that into a nice list and saves it in very compact form.

```
# function to make a list with all the information necessary to do predictions
#   using the HMD-calibrated SVD-Comp
make.models <- function(allModels.f,allModels.sm.f,allModels.m,allModels.sm.m) {

  # initialize array to hold components
  components <- array(
    data=rep(0,880),
    dim=c(2,4,110),
    dimnames=list(
